

IS ANYONE HOME?

Your guide to exoplanet habitability
(for life as we know it)

STARS

ACTIVITY

- Stars release UV light, X-rays, and energetic particles, all of which can be harmful to life and strip away a planet's atmosphere.
- Some stars are more active than others.

AGE

- Young stars are often very active.
- Old stars expand quickly, engulfing nearby planets.

SIZE AND TYPE

- Some stars may be good for life, others may just be too extreme. These stellar factors determine where a habitable planet might be found and if life could even survive there at all.
- More Active and Longer-lasting
- Calmer and Shorter-lived
- Planets around small stars must be very close to their volatile hosts. Any life could be fried by stellar activity.
- Planets around large stars have to be far from their star and may not have enough time to develop life before the star dies.

PLANETS

ORBITS

- How and where a planet orbits its star is very important for its habitability.
- Habitable planets are likely found in the Goldilocks zone, meaning they're just the right distance from their star where liquid water may exist on the surface.

- Planets in eccentric orbits — or those experiencing dramatic changes in tilt — could have extreme seasons.
- Planets which orbit too closely to each other can affect the stability of each other's orbits and climates.

PLANET SIZE

- The size of a planet plays a large role in how much atmosphere it can hold.
- Small planets aren't able to keep stellar winds from blowing away an atmosphere.
- Planets that are too large hide their surfaces under atmospheres much thicker than Earth's.

MAGNETIC FIELDS

- On Earth, magnetic fields are produced by a spinning molten iron core.
- The field protects the planet's atmosphere from harmful activity from its star, which could impact the habitability for some forms of life.

COMPOSITION

- A planet must include the elements needed for life.
- Water, especially liquid water, is considered the key component for life.
- Radioactive elements help drive life-supporting processes like plate tectonics and magnetic field formation.
- But too much of them could disrupt the planet's chemistry, climate or plate tectonics.

ATMOSPHERE

TEMPERATE CLIMATE

- To keep oceans of liquid water, a planet requires a temperate climate. This means an atmosphere that supplies the right amount of global warming.
- Water (H₂O), carbon dioxide (CO₂), methane (CH₄), clouds and particles all can impact surface temperature.
- Detecting gases that are made by life is one way we could confirm a planet's habitability

WATER

ICE CAPS

- As on Earth, ice caps help regulate the climate of a planet by reflecting energy from its star.
- The larger the ice caps, the colder the atmosphere, meaning more ice can form.
- If the caps become too large, they can lead to an extreme ice age!

ICY OCEAN WORLDS

- Like Jupiter's moon Europa, exoplanets may have vast oceans hidden beneath thick layers of ice.
- It's possible that life thrives in these oceans if tidal heating and radioactivity keep them warm. The ice would protect life from dangerous activity from the star.

TIDES

- Tides on Earth are powered by the Moon and the Sun. They help stabilize the orbit and tilt of the planet, as well as slow its spin.
- If the tides are too strong the planet could experience tidal locking, which would dramatically alter the planet's climate.

OCEANS

- Water is essential for life as we know it because it acts as a solvent for organic chemistry, the foundation of life on Earth.
- Deep oceans can protect early life from an active star. They also help stabilize the climate and transport energy across its surface.

HYDROTHERMAL VENTS

- These vents are like deep sea mini volcanoes that create nutrient-rich hot water.
- They are possible places for early life to form.
- Tides help warm oceans, drive currents, circulate nutrients all over the planet, and influence plate tectonics.

SURFACE

CARBON CYCLE

- The carbon cycle is a planet's way of recycling carbon atoms. The process involves the atmosphere, oceans, volcanoes, and other factors that change over time.
- As a greenhouse gas, carbon dioxide (CO₂) directly affects how much heat the atmosphere retains.
- The carbon cycle causes carbon dioxide levels in the atmosphere to rise and fall.

PLATE TECTONICS

- The plates carry important elements that have settled on the seafloor.
- As the plates move into the interior and melt, these elements are then brought back to the surface by volcanic activity.

VOLCANISM

- Volcanoes bring important elements like CO₂, nitrogen, and water from deep within a planet to the surface in a process called mantle outgassing.
- Without volcanic activity putting CO₂ in a planet's atmosphere, it will likely be too cold for life.
- The right level of volcanic activity supports life by delivering important elements to the surface.
- With too much ash in an atmosphere, sunlight could be blocked from the surface, affecting life.
- At 1-10 million times Earth's current volcanic activity, vast lakes of lava may form on the surface.

INTERIOR

CORE

- A liquid iron core is important for protecting life on a planet's surface. The movement of molten iron generates a magnetic field, which shields the atmosphere from stellar activity.
- Some planets with iron cores, like Earth, start with a completely liquid core which crystallizes over time.
- For planets with small cores, the core may completely solidify, turning off the magnetic field.
